

Ve492: Introduction to Artificial Intelligence

Bayesian Networks: Representation

Paul Weng

UM-SJTU Joint Institute

Slides adapted from <http://ai.berkeley.edu>, CMU, AIMA, UM

Probabilistic Models

- ❖ Models describe how (a portion of) the world works
- ❖ **Models are always simplifications**
 - ❖ May not account for every variable
 - ❖ May not account for all interactions between variables
 - ❖ “All models are wrong; but some are useful.”
– George E. P. Box
- ❖ **What do we do with probabilistic models?**
 - ❖ We (or our agents) need to reason about unknown variables, given evidence
 - ❖ Example: explanation (diagnostic reasoning)
 - ❖ Example: prediction (causal reasoning)

Bayes' Nets: Big Picture

Bayes' Nets: Big Picture

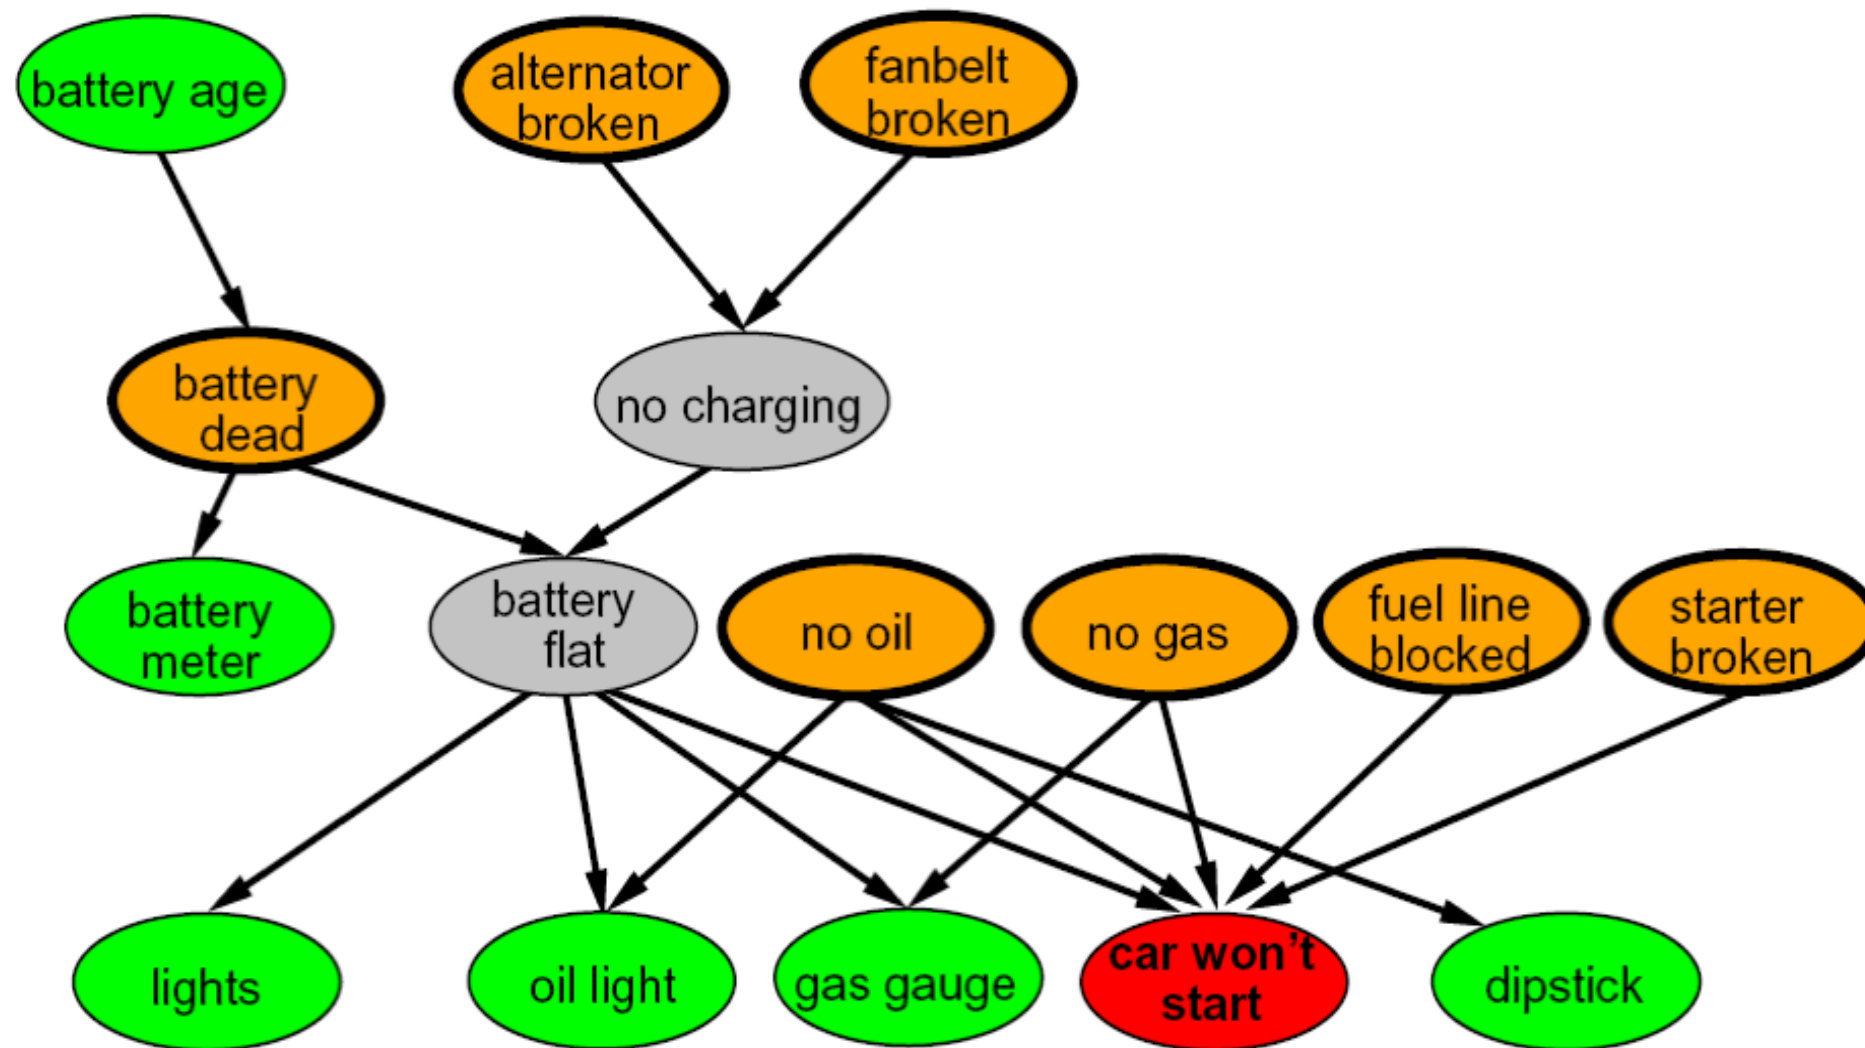

- ❖ Two problems with using full joint distribution tables as our probabilistic models:
 - ❖ Unless there are only a few variables, the joint is WAY too big to represent explicitly
 - ❖ Hard to learn (estimate) anything empirically about more than a few variables at a time
- ❖ **Bayes' nets:** a technique for describing complex joint distributions (models) using simple, local distributions (conditional probabilities)
 - ❖ More properly called **graphical models**
 - ❖ We describe how variables locally interact
 - ❖ Local interactions chain together to give global, indirect interactions

Example Bayes' Net: Insurance

Example Bayes' Net: Car

Bayes' Net Notation

- ❖ **Nodes: variables (with domains)**

- ❖ Can be assigned (observed) or unassigned (unobserved)

- ❖ **Arcs: interactions**

- ❖ Similar to CSP constraints
- ❖ Indicate “direct influence” between variables
- ❖ Formally: encode conditional independence (more later)

- ❖ For now: imagine that arrows mean direct causation (in general, they don't!)

Example: Coin Flips

- ❖ N independent coin flips

X_1

X_2

...

X_n

- ❖ No interactions between variables: **absolute independence**

Example: Traffic

- ❖ Variables:

- ❖ R: It rains
- ❖ T: There is traffic

- ❖ Model 1: independence

- ❖ Model 2: rain causes traffic

- ❖ Why is an agent using model 2 better?

Example: Traffic II

❖ Let's build a causal graphical model!

❖ Variables

- ❖ T: Traffic
- ❖ R: It rains
- ❖ L: Low pressure
- ❖ D: Roof drips
- ❖ B: Ballgame
- ❖ C: Cavity

Example: Alarm Network

❖ Variables

- ❖ B: Burglary
- ❖ A: Alarm goes off
- ❖ M: Mary calls
- ❖ J: John calls
- ❖ E: Earthquake!

Bayes' Net Semantics

Bayes' Net Semantics

- ❖ A set of nodes, one per variable
- ❖ A directed, acyclic graph
- ❖ A conditional distribution for each node
 - ❖ A collection of distributions over X , one for each combination of parents' values
- ❖ CPT: conditional probability table
- ❖ Description of a noisy “causal” process

$$P(X|a_1 \dots a_n)$$

$$P(X|A_1 \dots A_n)$$

A Bayes net = Topology (graph) + Local Conditional Probabilities

Probabilities in BNs

- ❖ Bayes' nets **implicitly** encode joint distributions
- ❖ As a product of local conditional distributions
- ❖ To see what probability a BN gives to a full assignment, multiply all the relevant conditionals together:

$$P(x_1, x_2, \dots, x_n) = \prod_{i=1}^n P(x_i | \text{parents}(X_i))$$

- ❖ Example:

$$P(+cavity, +catch, -toothache)$$

Probabilities in BNs

- ❖ Why are we guaranteed that setting

$$P(x_1, x_2, \dots, x_n) = \prod_{i=1}^n P(x_i | \text{parents}(X_i))$$

results in a proper joint distribution?

- ❖ Chain rule (valid for all distributions): $P(x_1, x_2, \dots, x_n) = \prod_{i=1}^n P(x_i | x_1 \dots x_{i-1})$

- ❖ Assume conditional independences: $P(x_i | x_1, \dots, x_{i-1}) = P(x_i | \text{parents}(X_i))$

→ Consequence:
$$P(x_1, x_2, \dots, x_n) = \prod_{i=1}^n P(x_i | \text{parents}(X_i))$$

- ❖ Not every BN can represent every joint distribution

- ❖ The topology enforces certain conditional independencies

Example: Coin Flips

$$P(h, h, t, h) =$$

Only distributions whose variables are absolutely independent can be represented by a Bayes' net with no arcs.

Example: Traffic

$P(R)$

$+r$	$1/4$
$-r$	$3/4$

$$P(+r, -t) =$$

$P(T|R)$

$+r$	$+t$	$3/4$
	$-t$	$1/4$
$-r$	$+t$	$1/2$
	$-t$	$1/2$

Quiz: Alarm Network

B	P(B)
+b	0.001
-b	0.999

E	P(E)
+e	0.002
-e	0.998

A	J	P(J A)
+a	+j	0.9
+a	-j	0.1
-a	+j	0.05
-a	-j	0.95

A	M	P(M A)
+a	+m	0.7
+a	-m	0.3
-a	+m	0.01
-a	-m	0.99

$$P(+b, -e, +a, -j, +m) =$$

B	E	A	P(A B,E)
+b	+e	+a	0.95
+b	+e	-a	0.05
+b	-e	+a	0.94
+b	-e	-a	0.06
-b	+e	+a	0.29
-b	+e	-a	0.71
-b	-e	+a	0.001
-b	-e	-a	0.999

Example: Traffic

❖ Causal direction

$P(R)$

+r	1/4
-r	3/4

$P(T|R)$

+r	+t	3/4
	-t	1/4
-r	+t	1/2
	-t	1/2

$P(T, R)$

+r	+t	3/16
+r	-t	1/16
-r	+t	6/16
-r	-t	6/16

Example: Reverse Traffic

❖ Reverse causality?

$P(T)$

+t	9/16
-t	7/16

$P(R|T)$

+t	+r	1/3
	-r	2/3
-t	+r	1/7
	-r	6/7

$P(T, R)$

+r	+t	3/16
+r	-t	1/16
-r	+t	6/16
-r	-t	6/16

Causality?

- ❖ When Bayes' nets reflect the true causal patterns:

- ❖ Often simpler (nodes have fewer parents)
- ❖ Often easier to think about
- ❖ Often easier to elicit from experts

- ❖ BNs need not actually be causal

- ❖ Sometimes no causal net exists over the domain (especially if variables are missing)
- ❖ E.g. consider the variables *Traffic* and *Drips*
- ❖ End up with arrows that reflect correlation, not causation

- ❖ What do the arrows really mean? $P(x_i|x_1, \dots, x_{i-1}) = P(x_i|parents(X_i))$

- ❖ Topology may happen to encode causal structure
- ❖ **Topology really encodes conditional independence**

Bayes' Nets

- ❖ So far: how a Bayes' net encodes a joint distribution
 - ❖ Key property: conditional independence
- ❖ Next: how to answer queries about that distribution
 - ❖ Queries about conditional independence and influence
- ❖ After that: how to answer numerical queries (inference)
 - ❖ Queries about (conditional) probabilities
